

The Lua language (v5.1)

Reserved identifiers and comments

and	break	do	false	else	elseif	end	false	for	function	if	in
local	nil	not	or	repeat	return	then	true	until	while		
---	...	comment	end of line		-[= ...]=	multi-line comment	(zero or multiple \leq are valid)				
X is "reserved" (by convention) for constants (with X #!										usual Unix shebang; Lua ignores whole first line if this being any sequence of uppercase letters starts the line.	
Types (the string values are the possible results of base library function type())	"nil"	"boolean"	"number"	"string"	"table"	"function"	"thread"	"userdata"			

Note: for type boolean, nil and false count as false; everything else is true (including 0 and "").

Strings and escape sequences

... and "..."	string delimiters; interpret escapes. \a bell \b backspace \f form feed \l backslash \\" d. quote \\' quote	[=...]=	\n newline \t horiz. tab \v vert. tab \ddd decimal (up to 3 digits) \sq. bracket	multi line string; escape sequences are ignored. \r return \f object as a function)
Operators, decreasing precedence				
& (right associative, math library required)	# (length of strings and tables)	- (unary)	%	
not	/			
*		-		
+				
.. (string concatenation, right associative)	<=	=		
<				
and (stops on false or nil, returns last evaluated value)				
or (stops on true (not false or nil), returns last evaluated value)				

Assignment and coercion

a = 5 b = "hi"	simple assignment; variables are not typed and can hold different types. Local variables are lexically scoped; their scope begins after the full declaration (so that local a = 5).
local a = a	multiple assignments are supported
a, b = 1, 2, 3	swap values: right hand side is evaluated before assignment takes place
a, b = b, a	excess values on right hand side nil ("") are evaluated but discarded
a, b = 4, 5, '6'	for missing values on right hand side nil is assumed
a, b = "there"	destroys a ; its contents are eligible for garbage collection if unreferenced.
a = nil	if z is not defined it is nil , so nil is assigned to a (destroying it)
a = z	numbers expected; strings are converted to numbers (a = 5)
a = "3" + "2"	strings expected, numbers are converted to strings (a = "32")
a = 3 .. 2	

Control structures

do block end	block; introduces local scope.
if exp then block {elseif exp then block} [else block] end	conditional execution loop as long as exp is true
while exp do block end	loop exits when exp becomes true; exp is in loop scope.
repeat block until exp	numerical loop; vars is local to loop.
for var = start, end [, step] do block end	iterator based for loop; vars are local to loop.
for vars in iterator do block end	mixed, fields/elements are t.x, t.y, t[1], t[2]
break	tables can contain others tables as fields

Table constructors

t = {}	creates an empty table and assigns it to t
t = {"yes", "no", "??"}	simple array; elements are t[1], t[2], t[3] . same as above, but with explicit fields
t = {[1] = "yes", [2] = "no", [3] = "?"}	sparse array with just two elements (no space wasted)
t = {[.990] = 3, [990] = 4}	hash table; fields are t["x"], t["y"] (or t.x, t.y) numerical function assigned to variable f
t = {x=5, y=10}	mixed, fields/elements are t.x, t.y, t[1], t[2] variable argument list, body accessed as ...
t = {msg = "choice", ["yes", "no", "??"}}	shortcut for t.name = function ... object function, gets obj as additional first argument self
function obj:name (args) body [return values] end	defines function and assigns to global variable name defines function as local to chunk anonymous function assigned to variable f variable argument list, body accessed as ...
function call	simple call, possibly returning one or more values
f(x)	shortcut for f("hello")
f'goodbye'	shortcut for f'goodbye'

Metatable operations (base library required)	
setmetatable (t, mt)	sets mt as metatable for t , unless t's metatable has a _metatable field, and returns t
rawget (t, i)	gets t[i] of t 's metatable or t's metatable or nil
rawset (t, i, v)	sets t[i] = v on a table without invoking metamethods
rawequal (t1, t2)	returns boolean (t1 == t2) without invoking metamethods
Metatable fields (for tables and userdata)	
add, __sub	sets handler h(a, b) for '+' and for binary '-'
mod	sets handler h(a, b) for '%'
pow	sets handler h(a, b) for '^'
len	sets handler h(a) for the '#' operator (userdata)
concat	sets handler h(a, b) for '..'
lt	sets handler h(a, b) for '<', '>' and possibly '<=','>='
gt	sets handler h(a, b) for '>' and possibly '>='
index	sets handler h(t, k) for access to non-existing field
newindex	sets handler h(t, k, v) for assignment to non-existing field
call	sets handler h(f, ...) for function call (using the object as a function)
gc	sets finalizer h(nd) for userdata (has to be set from C)
metatable	sets value to be returned by getmetatable()
The base library [no prefix]	
Environment and global variables	
getenv (ff)	if ff is a function, returns its environment; if ff is a number, returns the environment of function at level f (= current [default], 0 = global); if the environment has a field _env , returns that instead.
setenv (f, t)	sets environment for function f (or function at level f , 0 = current thread); if the original environment has a field _env raises an error. Returns function f if f ~= 0 .
G	global variable whose value is the global environment (that is, G, G == G)
VERSION	global variable containing the interpreter's version (e.g. "Lua 5.1")
Loading and executing	
require (pname)	loads a package, raises error if it can't be loaded
dofile ([filename])	loads and executes the contents of filename [default: standard input]; returns its returned values.
load (func [, chunkname])	loads a chunk (with chunk name set to name) using function func to get its pieces; returns a compiled chunk as function (or nil and error message).
loadfile (filename)	loads file filename ; return values like load() .
loadstring (s [, name])	loads string s (with chunk name set to name); return values like load() .
pcall (f [, args])	calls f() in protected mode; returns true and function results or false and error message.
xpcall (f, h)	as pcall() but passes error handler h instead of extra args; returns as pcall() but with the result of h() as error message, if any.
Simple output and error feedback	
print (args)	prints each of the passed args to stdout using tostring() (see below)
error (msg [, nl])	terminates the program or the last protected call (e.g. pcall()) with error message msg quoting level n [default: 1; current function]
assert (v [, msg])	calls error(msg) if v is nil or false [default msg : "assertion failed!"]
Information and conversion	
select (index, ...)	returns the arguments after argument number index or (if index is "#") the total number of arguments it received after index
type (x)	returns the type of x as a string (e.g. "nil", "string"); see Types above.
tonstring (x)	converts x to a string, using its metatable's _tonstring if available
tonumber (x [, b])	converts string x representing a number in base b [2..36; default: 10] to a number, or nil if invalid; for base 10 accepts full format (e.g. "1.5e6").
unpack (t)	returns t[1].t[n] (n = #t) as separate values
Iterators	
ipairs (t)	returns an iterator getting index , value pairs of array t in numerical order
pairs (t)	returns an iterator getting key , value pairs of table t in an unspecified order
next (t [, idx])	if idx is nil [default] returns first index , value pair of table t ; if idx is the previous index returns next index , value pair or nil when finished.

Garbage collection

<code>collectgarbage (opt, [arg])</code>	generic interface to the garbage collector; <code>opt</code> defines function performed.
--	--

Modules and the package library [package]

<code>module (name, ...)</code>	creates module <code>name</code> . If there is a table in <code>package.loaded[name]</code> , this table is the module. Otherwise, if there is a global table <code>name</code> , this table is the module. Otherwise creates a new table and sets it as the value of the global <code>name</code> and the value of <code>package.loaded[name]</code> . Optional arguments are functions to be applied over the module.
<code>package.loadlib (lib, func)</code>	loads dynamic library <code>lib</code> (.so or .dll) and returns function <code>func</code> (or <code>nil</code> and error message)
<code>package.path, package.cpath</code>	contains the paths used by <code>require()</code> to search for a Lua or C loader, respectively
<code>package.loaded</code>	a table used by <code>require</code> to control which modules are already loaded (see module)
<code>package.preload</code>	a table to store loaders for specific modules (see require)
<code>package.seccall (module)</code>	sets a metatable for <code>module</code> with its <code>_index</code> field referring to the global environment
<h2>The coroutine library [coroutine]</h2>	
<code>coroutine.create (f)</code>	creates a new coroutine with Lua function <code>f</code> as body and returns it
<code>coroutine.resume (co, args)</code>	starts or continues running coroutine <code>co</code> , passing <code>args</code> to it; returns <code>true</code> (and possibly values) if <code>co</code> calls <code>coroutine.yield()</code> or terminates or <code>false</code> and an error message.
<code>coroutine.yield (args)</code>	suspends execution of the calling coroutine (not from within C functions, metamethods or iterators); any <code>args</code> become extra return values of <code>coroutine.resume()</code> .
<code>coroutine.status (co)</code>	returns the status of coroutine <code>co</code> : either "running", "suspended" or "dead"
<code>coroutine.running ()</code>	returns the running coroutine or <code>nil</code> when called by the main thread
<code>coroutine.wrap (f)</code>	creates a new coroutine with Lua function <code>f</code> as body and returns a function; this function will act as <code>coroutine.resume()</code> without the first argument and the first return value, propagating any errors.
<h2>The table library [table]</h2>	
<code>table.insert (t, [i], v)</code>	inserts <code>v</code> at numerical index <code>i</code> [default: after the end] in table <code>t</code>
<code>table.remove (t, [i])</code>	removes element at numerical index <code>i</code> [default: last element] from table <code>t</code> ; returns the removed element or <code>nil</code> on empty table.
<code>table.maxn (t)</code>	returns the largest positive numerical index of table <code>t</code> or zero if <code>t</code> has no positive indices
<code>table.sort (t, [c])</code>	sorts (in place) elements from <code>t[1]</code> to <code>#t</code> , using compare function <code>c(e1, e2)</code> [default: ' <code><</code> ']
<code>table.concat (t, s [, i [, j]])</code>	returns a single string made by concatenating table elements <code>t[i]</code> to <code>t[j]</code> [default: <code>i = 1, j = #t</code>] separated by string <code>s</code> ; returns empty string if no elements exist or <code>i > j</code> .
<h2>The mathematical library [math]</h2>	
 Basic operations	
<code>math.abs (x)</code>	returns the absolute value of <code>x</code>
<code>math.mod (x, y)</code>	returns the remainder of <code>x / y</code> as a rounded-down integer, for <code>y ~= 0</code>
<code>math.floor (x)</code>	returns <code>x</code> rounded down to the nearest integer
<code>math.ceil (x)</code>	returns <code>x</code> rounded up to the nearest integer
<code>math.min (args)</code>	returns the minimum value from the <code>args</code> received
<code>math.max (args)</code>	returns the maximum value from the <code>args</code> received
 Exponential and logarithmic	
<code>math.sqrt (x)</code>	returns the square root of <code>x</code> , for <code>x >= 0</code>
<code>math.pow (x, y)</code>	returns <code>x</code> raised to the power of <code>y</code> , i.e. <code>x^y</code> ; if <code>x < 0</code> , <code>y</code> must be integer.
<code>math.floor (x)</code>	global function added by the math library to make operator ' <code>\w\w</code> ' work
<code>math.exp (x)</code>	returns <code>e</code> (base of natural log) raised to the power of <code>x</code> , i.e. <code>e^x</code>
<code>math.log (x)</code>	returns the natural logarithm of <code>x</code> , for <code>x >= 0</code>
<code>math.log10 (x)</code>	returns the base-10 logarithm of <code>x</code> , for <code>x >= 0</code>
 Trigonometrical	
<code>math.deg (a)</code>	converts angle <code>a</code> from radians to degrees
<code>math.rad (a)</code>	converts angle <code>a</code> from degrees to radians
<code>math.pi</code>	constant containing the value of pi
<code>math.sin (a)</code>	returns the sine of angle <code>a</code> (measured in radians)
<code>math.cos (a)</code>	returns the cosine of angle <code>a</code> (measured in radians)
<code>math.tan (a)</code>	returns the tangent of angle <code>a</code> (measured in radians)
<code>math.asin (x)</code>	returns the arc sine of <code>x</code> in radians, for <code>x</code> in [-1, 1]
<code>math.acos (x)</code>	returns the arc cosine of <code>x</code> in radians, for <code>x</code> in [-1, 1]
<code>math.atan (x)</code>	returns the arc tangent of <code>x</code> in radians
<code>math.atan2 (y, x)</code>	similar to <code>math.atan(y / x)</code> but with quadrant and allowing <code>x = 0</code>
 Splitting on powers of 2	
<code>math.frexp (x)</code>	splits <code>x</code> into normalized fraction and exponent of 2 and returns both
<code>math.ldexp (x, y)</code>	returns <code>x * (2 ^ y)</code> with <code>x</code> = normalized fraction, <code>y</code> = exponent of 2

Pseudo-random numbers

<code>math.random (n [, m])</code>	returns a pseudo-random number in range [0, 1] if no arguments given; in range [1, <code>n</code>] if <code>n</code> is given, in range [<code>n</code> , <code>m</code>] if both <code>n</code> and <code>m</code> are passed.
<code>math.randomseed (n)</code>	sets a seed <code>n</code> for random sequence (same seed = same sequence)
 <h2>The string library [string]</h2>	
 Basic operations	Note: string indexes extend from 1 to <code>#string</code> , or from end of string if negative (index -1 refers to the last character). Note: the string library sets a metatable for strings, where the <code>_index</code> field points to the string table. String functions can be used in object-oriented style, e.g. <code>string.len(s)</code> can be written <code>s:len()</code> ; literals have to be enclosed in parentheses, e.g. <code>("xyz").len()</code> .
<code>string.len (s)</code>	returns the length of string <code>s</code> , including embedded zeros (see also <code>#</code> operator)
<code>string.sub (s, i [, j])</code>	returns the substring of <code>s</code> from position <code>i</code> to <code>j</code> [default: -1] inclusive
<code>string.rep (s, n)</code>	returns a string made of <code>n</code> concatenated copies of string <code>s</code>
<code>string.upper (s)</code>	returns a copy of <code>s</code> converted to uppercase according to locale
<code>string.lower (s)</code>	returns a copy of <code>s</code> converted to lowercase according to locale
 Character codes	
<code>string.byte (s [, i [, j]])</code>	returns the platform-dependent numerical code (e.g. ASCII) of characters <code>s[i], s[i+1], ..., s[j]</code> . The default value for <code>i</code> is 1; the default value for <code>j</code> is <code>i</code> .
<code>string.char (args)</code>	returns a string made of the characters whose platform-dependent numerical codes are passed as <code>args</code>
 Function storage	
<code>string.dump (f)</code>	returns a binary representation of function <code>f()</code> , for later use with <code>loadstring()</code> (<code>f()</code> must be a Lua function with no upvalues)
 Formatting	
<code>string.format (s [, args])</code>	returns a copy of <code>s</code> where formatting directives beginning with '%' are replaced by the value of arguments <code>args</code> , in the given order (see <i>Formatting directives</i> below)
 Formatting directives for string.format	
<code>% [flags] [field_width].[precision] type</code>	
 Formatting field types	
<code>%d</code>	decimal integer
<code>%o</code>	octal integer
<code>%f</code>	hexadecimal integer, uppercase if <code>%X</code>
<code>%e</code>	floating-point in exp. Form <code>[+-]nnnn.nnnn e [+ -]nnnn</code> , uppercase if <code>%E</code>
<code>%g</code>	floating-point as <code>%e</code> if exp. < -4 or >= precision, else as <code>%f</code> ; uppercase if <code>%G</code>
<code>%c</code>	character having the (system-dependent) code passed as integer
<code>%s</code>	string with no embedded zeros
<code>%q</code>	string with double quotes, with all special characters escaped
<code>%%</code>	<code>%_</code> character
 Formatting flags	
<code>-</code>	left-justifies within field <code>width</code> [default: right-justify]
<code>+</code>	prepends sign (only applies to numbers)
<code>(space)</code>	prepends sign if negative, else blank space
<code>#</code>	adds <code>'0x'</code> before <code>%X</code> , force decimal point for <code>%e</code> , <code>%f</code> , leaves trailing zeros for <code>%g</code>
 Formatting field width and precision	
<code>n</code>	puts at least <code>n</code> (<100) characters, pad with blanks
<code>0n</code>	puts at least <code>n</code> (<100) characters, left-pad with zeros
<code>.n</code>	puts at least <code>n</code> (<100) digits for integers; rounds to <code>n</code> decimals for floating-point; puts no more than <code>n</code> (<100) characters for strings.
 Formatting examples	
<code>string.format ("results: %d, %d", 13, 27)</code>	results: 13, 27
<code>string.format ("<%-6d>", 13)</code>	< 13>
<code>string.format ("<%05d>", 13)</code>	<13> >
<code>string.format ("<%05d>", 13)</code>	<00013>
<code>string.format ("<%06.3d>", 13)</code>	< 013>
<code>string.format ("<%0e>", math.pi)</code>	<3.141593>
<code>string.format ("<%0e>", math.pi)</code>	<3.141592653589793>
<code>string.format ("<%04f>", math.pi)</code>	<3.1416>
<code>string.format ("<%09.4f>", math.pi)</code>	< 3.1416>
<code><@></code>	<@>
<code><good></code>	<good>
<code>"she said \"hi\""</code>	"she said "hi"\\"

Finding, replacing, iterating (for the Patterns see below)

<code>string.find(s, p [, i, dl])</code>	returns first and last position of pattern p in string s , or nil if not found, starting search at position i [default: 1]; returns captures as extra results. If d is true, treat pattern as plain string.
<code>string.gsub(s, p)</code>	returns an iterator getting next occurrence of pattern p (or its captures) in string s as substring(s) matching the pattern.
<code>string.gsub(s, p [, n])</code>	returns a copy of s with up to n [default: all] occurrences of pattern p (or its captures) replaced by r if r is a string. (r can include references to captures in the form <code>%n</code>). If r is a function r() is called for each match and receives captured substrings; it should return the replacement string. If r is a table, the captures are used as fields into the table. The function returns the number of substitutions made as second result.
<code>string.match(s, p [, i])</code>	returns captures of pattern p in string s (or the whole match if p specifies no captures) or nil if p does not match s ; starts search at position i [default: 1].

Patterns and pattern items

General pattern format: `pattern_item [pattern_items]`

`cc` matches a single character in the class `cc` (see *Pattern character classes* below)

`cc*` matches zero or more characters in the class `cc`; matches longest sequence (greedy).

`cc-` matches zero or more characters in the class `cc`; matches shortest sequence (non-greedy).

`cc?` matches zero or one character in the class `cc`.

`%n/n` matches the *n*-th captured string (*n* = 1..9, see *Pattern captures*)

`%hxy` matches the balanced string from character `x` to character `y` (e.g. `%hB` for nested parentheses)

`$` anchors pattern to start of string, must be the first item in the pattern

`$` anchors pattern to end of string, must be the last item in the pattern

Captures

`(pattern)` stores substring matching *pattern* as capture `%1..%9`, in order of opening parentheses

`()` stores current string position as capture

Pattern character classes

<code>.</code>	any character	<code>%A</code>	any non-letter
<code>%oa</code>	any letter	<code>%C</code>	any non-control character
<code>%oc</code>	any control character	<code>%D</code>	any non-digit
<code>%od</code>	any digit	<code>%L</code>	any non-(lowercase letter)
<code>%ol</code>	any lowercase letter	<code>%P</code>	any non-punctuation character
<code>%op</code>	any punctuation character	<code>%S</code>	any non-whitespace character
<code>%os</code>	any whitespace character	<code>%U</code>	any non-(uppercase letter)
<code>%ou</code>	any uppercase letter	<code>%W</code>	any non-alphanumeric character
<code>%ow</code>	any alphanumeric character	<code>%X</code>	any non-hexadecimal digit
<code>%ox</code>	any hexdecimal digit	<code>%Z</code>	any non-zero character
<code>%oz</code>	the bye value zero	<code>x</code>	if <code>x</code> is a symbol the symbol itself if <code>x</code> is a character not in <code>set</code>
<code>%ox</code>	any character in any of the given classes; can also be a range [<code>i1..i2</code>], e.g. [<code>a..z</code>].	<code>[^set]</code>	any character not in <code>set</code>

Pattern examples

<code>string.find("Lua is great!", "is")</code>	5	6	6
<code>string.find("Lua is great!", "%as")</code>	4	4	4
<code>string.gsub("Lua is great!", "%s", "")</code>	Lua-is-great!	Lua-is-great!	Lu
<code>string.gsub("Lua is great!", "%s", "***")</code>	L*****	L*****	L*****
<code>string.gsub("Lua is great!", "%a+", "***")</code>	***	***	***
<code>string.gsub("Lua is great!", "(.)", "%1%1")</code>	L	L	LL
<code>string.gsub("Lua is great!", "%b", "")</code>	L!	L!	L!
<code>string.gsub("Lua is great!", "%a", " LUA")</code>	LUA is great!	LUA is great!	LUA is great!
<code>string.gsub("Lua is great!", "%a", " LUA")</code>	LUA is great!	LUA is great!	LUA is great!
<code>function(s) return string.upper(s) end</code>			

The I/O library [io]

Complete I/O

<code>io.open(fn [, ml])</code>	opens file with name fn in mode ml : " <code>r</code> " = read [default], " <code>w</code> " = write " <code>a</code> " = append, " <code>r+</code> " = update-preserve, " <code>w+</code> " = update-erase, " <code>a+</code> " = update-append (add trailing "b" for binary mode on some systems); returns a file object (a userdata with a C handle).
<code>file.close()</code>	closes file
<code>file.read(formats)</code>	returns a value from file for each of the passed formats: " <code>...n</code> " = reads a number, " <code>*n</code> " = reads the whole file as a string from current position (returns "" at end of file), " <code>!n</code> " = reads a line (nil at end of file) [default file] [default offset: zero]; returns new current position in file .

`io.lines([fn])` returns an iterator function for reading **file** line by line; the iterator does not close the file when finished.

`io.tmpfile()` returns the difference between two values returned by `os.time()`

`os.dirftime(t2, t1)` returns the difference between two values returned by `os.time()`

`os.execute(cmd)` calls a system shell to execute the string **cmd** as a command; returns a system-dependent status code.

`os.exit([code])` terminates the program returning **code** [default: success]

`os.getenv([var])` returns a string with the value of the environment variable **var** or **nil** if no such variable exists

`os.setlocale(s [, c])` sets the locale described by string **s** for category **c**: "all", "collate", "ctype", "monetary", "numeric" or "time" [default: "all"]; returns the name of the locale or **nil** if it can't be set.

`os.remove(fn)` deletes the file **fn**; in case of error returns **nil** and error description.

`os.rename(of, nf)` renames file **of** to **nf**; in case of error returns **nil** and error description.

`os.tmpname()` returns a string usable as name for a temporary file; subject to name conflicts, use `io.tmpfile()` instead.

Date/time

<code>os.clock()</code>	returns an approximation of the amount in seconds of CPU time used by the program
<code>os.time([tt])</code>	returns a system-dependent number representing date/time described by table tt [default: current]; tt must have fields year , month , day , min , sec , isdst (daylight saving, boolean). On many systems the returned value is the number of seconds since a fixed point in time (the "epoch").
<code>os.date([fmt [, t]])</code>	returns a table or a string describing date/time t (should be a value returned by <code>os.time()</code> [default: current date/time]), according to the format string fmt [default: date/time according to locale settings]; if fmt is "%s" or "%*", returns a table with fields year (yyyy), month (1..12), day (1..31), hour (0..23), min (0..59), sec (0..60), isdst (true = daylight saving, false = standard time), tm (table with fields year , month , day , hour , min , sec , isdst); if fmt is "%a" or "%A", returns a string with the day of the week (Sunday = 1, Saturday = 7); if fmt is "%w", returns a string with the day of the week (Sunday = 0, Saturday = 6); if fmt is "%p", returns AM or PM.
<code>os.dirftime(t2, t1)</code>	returns the difference between two values returned by <code>os.time()</code>

`os.execute(cmd)` calls a system shell to execute the string **cmd** as a command; returns a system-dependent status code.

`os.exit([code])` terminates the program returning **code** [default: success]

`os.getenv([var])` returns a string with the value of the environment variable **var** or **nil** if no such variable exists

`os.setlocale(s [, c])` sets the locale described by string **s** for category **c**: "all", "collate", "ctype", "monetary", "numeric" or "time" [default: "all"]; returns the name of the locale or **nil** if it can't be set.

`os.remove(fn)` deletes the file **fn**; in case of error returns **nil** and error description.

`os.rename(of, nf)` renames file **of** to **nf**; in case of error returns **nil** and error description.

`os.tmpname()` returns a string usable as name for a temporary file; subject to name conflicts, use `io.tmpfile()` instead.

`os.dirftime(t2, t1)` returns the difference between two values returned by `os.time()`

`os.execute(cmd)` calls a system shell to execute the string **cmd** as a command; returns a system-dependent status code.

`os.exit([code])` terminates the program returning **code** [default: success]

`os.getenv([var])` returns a string with the value of the environment variable **var** or **nil** if no such variable exists

`os.setlocale(s [, c])` sets the locale described by string **s** for category **c**: "all", "collate", "ctype", "monetary", "numeric" or "time" [default: "all"]; returns the name of the locale or **nil** if it can't be set.

`os.remove(fn)` deletes the file **fn**; in case of error returns **nil** and error description.

`os.rename(of, nf)` renames file **of** to **nf**; in case of error returns **nil** and error description.

`os.tmpname()` returns a string usable as name for a temporary file; subject to name conflicts, use `io.tmpfile()` instead.

`os.dirftime(t2, t1)` returns the difference between two values returned by `os.time()`

Time formatting directives (most used, portable features):

<code>%c</code>	date/time (locale)	<code>%X</code>	time only (locale)
<code>%x</code>	date only (locale)	<code>%Y</code>	year (yyyy)
<code>%y</code>	year (nn)		
<code>%j</code>	day of year (001..366)		
<code>%m</code>	month (01..12)		
<code>%b</code>	abbreviated month name (locale)	<code>%B</code>	full name of month (locale)
<code>%d</code>	day of month (01..31)		
<code>%U</code>	week number (01..53), Sunday-based	<code>%W</code>	week number (01..53), Monday-based
<code>%w</code>	weekday (0..6), 0 is Sunday		
<code>%a</code>	abbreviated weekday name (locale)	<code>%A</code>	full weekday name (locale)
<code>%H</code>	hour (00..23)	<code>%I</code>	hour (01..12)
<code>%P</code>	either AM or PM		
<code>%M</code>	minute (00..59)		
<code>%S</code>	second (00..61)		
<code>%Z</code>	time zone name, if any		

The debug library [debug]

Basic functions

<code>debug.debug()</code>	enters interactive debugging shell (type <code>cont</code> to exit); local variables cannot be accessed directly.
<code>debug.getinfo(f [, w])</code>	returns a table with information for function <code>f</code> or for function at level <code>f[1 = caller]</code> , or <code>nil</code> if invalid level (see <i>Result fields for getinfo</i> below); characters in string <code>w</code> select one or more groups of fields (default: all) (see <i>Options for getinfo</i> below).
<code>debug.getlocal(n, i)</code>	returns name and value of local variable at index <code>i</code> (from 1, in order of appearance) of the function at stack level <code>n</code> (1=caller); returns <code>nil</code> if <code>i</code> is out of range, raises error if <code>n</code> is out of range.
<code>debug.getupvalue(f, i)</code>	returns name and value of upvalue at index <code>i</code> (from 1, in order of appearance) of function <code>f</code> ; returns <code>nil</code> if <code>i</code> is out of range.
<code>debug.traceback(msg)</code>	returns a string with traceback of call stack, prepended by <code>msg</code>
<code>debug.setlocal(n, i, v)</code>	assigns value <code>v</code> to the local variable at index <code>i</code> (from 1, in order of appearance) of function <code>f</code> ; returns at stack level <code>n</code> (1=caller); returns <code>nil</code> if <code>i</code> is out of range, raises error if <code>n</code> is out of range.
<code>debug.setupvalue(f, i, v)</code>	assigns value <code>v</code> to the upvalue at index <code>i</code> (from 1, in order of appearance) of function <code>f</code> ; returns <code>nil</code> if <code>i</code> is out of range.
<code>debug.sethook(h, m [, n])</code>	sets function <code>h</code> as hook, called for events given in string (mask) <code>m</code> : "c" = function call, "r" = function return, "T" = new code line; also, a number <code>n</code> will call <code>h()</code> every <code>n</code> instructions; <code>h()</code> will receive the event type as first argument: "call", "return", "tail return", "line" (line number as second argument) or 'count'; use <code>debug.getinfo(2)</code> inside <code>h()</code> for info (not for "tail_return").
<code>debug.gethook()</code>	returns current hook function, mask and count set with <code>debug.sethook()</code>

Note: the debug library functions are not optimised for efficiency and should not be used in normal operation.

Result fields for debug.getinfo (character codes for argument w)

<code>n</code>	name of file (prefixed by '@') or string where the function was defined
<code>short_src</code>	short version of <code>source</code> , up to 60 characters
<code>linedefined</code>	line of source where the function was defined
<code>what</code>	"Lua" = Lua function, "C" = C function, "main" = part of main chunk
<code>name</code>	name of function, if available, or a reasonable guess if possible
<code>nameewhat</code>	meaning of <code>name</code> : "global", "local", "method", "field" or ""
<code>nups</code>	number of upvalues of the function
<code>func</code>	the function itself

Options for debug.getinfo (character codes for argument w)

<code>n</code>	returns fields <code>name</code> and <code>nameewhat</code>	<code>I</code>	returns field <code>currentline</code>
<code>f</code>	returns field <code>func</code>	<code>u</code>	returns field <code>upvalues</code>
<code>S</code>	returns fields <code>source</code> , <code>short_src</code> , <code>what</code> and <code>linedefined</code>		

The stand-alone interpreter

Command line syntax

<code>lua [options] [script [arguments]]</code>	
<code>-</code>	loads and executes <code>script</code> from standard input (no args allowed)
<code>-e stats</code>	executes the Lua statements in the literal string <code>stats</code> , can be used multiple times on the same line
<code>-l filename</code>	requires <code>filename</code> (loads and executes if not already done)
<code>-i</code>	enters interactive mode after loading and executing <code>script</code>
<code>-v</code>	prints version information
